CSS Task 4 – Box Model

Description

What is the CSS Box Model?

In CSS, every HTML element is treated like a box. The box model helps us understand how much space an element takes on a webpage. It has four parts: content, padding, border and margin.

1. Content

Content is the main part of the box. It can contain text, an image or other HTML content. We can set its width and height in CSS.

2. Padding

Padding is the space between the content and the border. If we increase the padding, there will be more space around the content inside the box.

3. Border

The border is the line around the content and padding. We can change its size, colour and style in CSS.

4. Margin

Margin is the space outside the border. It keeps distance between one box and another element on the page.

Width Experiment

For the width experiment, I kept the content width at 500px and changed the padding and border values. When padding or border is increased, the total width of the box also becomes bigger. This happens because the default box sizing adds padding and border to the content width.

Height Experiment

I did the same experiment with height. I set the content height to 300px, padding to 20px and border to 10px. The total height becomes 360px. If I increase the padding or border, the total height will also increase.

Example Calculation

For a box with width 500px, left and right padding of 40px each, and a 10px border on both sides, the total width is 600px.

For a box with height 300px, top and bottom padding of 20px each, and a 10px border on both sides, the total height is 360px. Margin is outside the border, so it is not included in these values.

Conclusion

After doing this task, I understood how the box model works. Content is the main area, padding gives space inside the box, border goes around it and margin gives space outside. Changing padding and border can change the total size of an element.
